VARIABLE TYPES

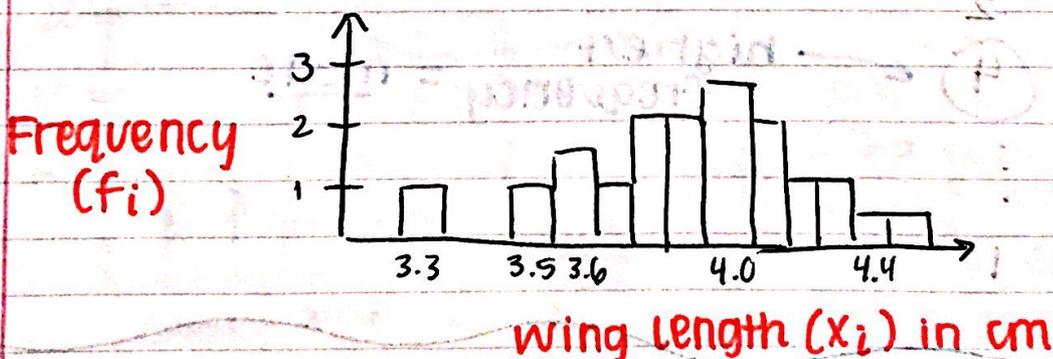

1.3 descriptive methods

→ sometimes useful and meaningful to summarize a variable by taking its mean

↳ The problem is that the mean is meaningful only for the age variable (bc its quantitative [ratio discrete]); the other two variables are qualitative [nominal].

RAW FREQUENCY DISTRIBUTION

- sort the data from smallest to largest
- see duplicate values
- keep track of the values of the variable & the raw frequencies

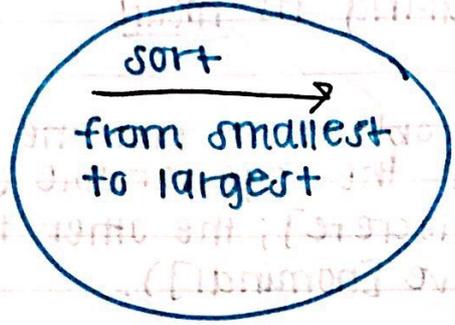

$y = \text{wing length (cm)}$

(order irrelevant)
Judgement

- 4.4
- 3.6
- 4.1
- 3.3
- ⋮
- 3.9 = $y_{24} = y_n$

$n = 24$

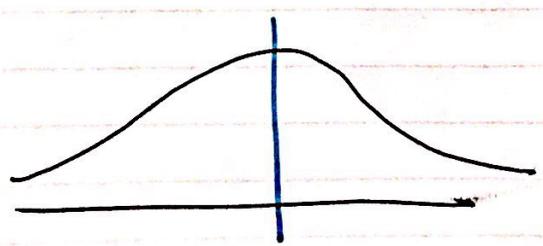

- 3.3
- 3.5
- 3.6
- 3.6
- 3.7
- ⋮
- 4.5

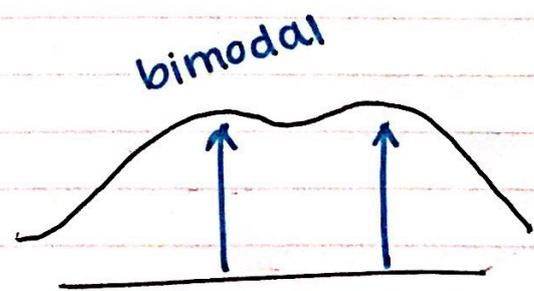

Value	count raw frequency
3.3	1
3.4	0
3.5	1
3.6	2
4.0	4
⋮	⋮
4.5	1

identical information

highest frequency = mode

mode

bimodal

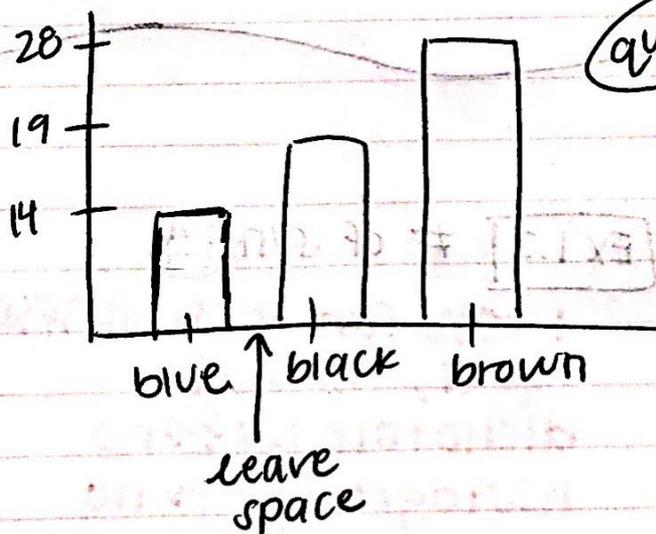

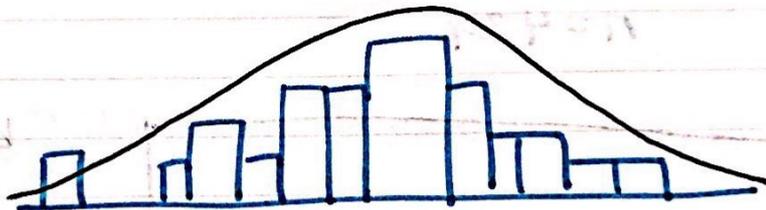

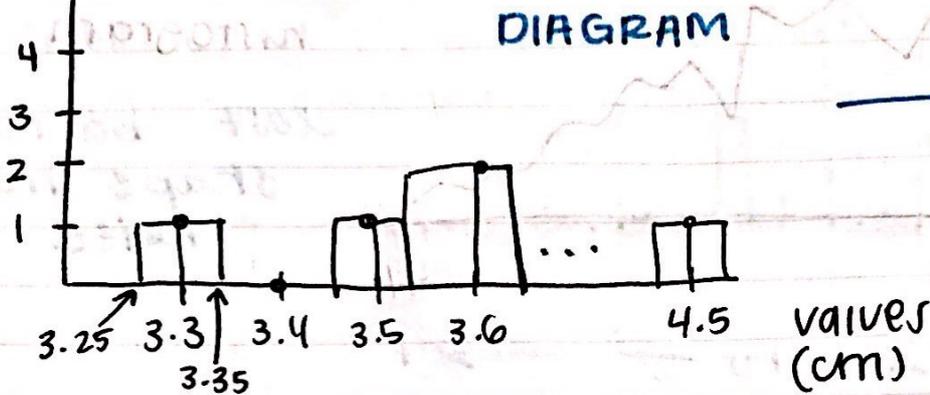

(multi)modal

(>1)

height of adults

histogram

lost basic
shape in
noise

$n = 424$

bad
histogram

lost ^{all} sense of shape
of distribution

more Graphical Examples

EX 1.1 | sparrow nests

1 row for each nest
qual, nominal
histogram? → no
bar graph? → yes
dichotomous? → no

EX 1.2 | # of sunfish

1 row for each sunfish
qual, ordinal
dichotomous? → no
histogram? → no
bar graph? → yes
